

Are energy storage and return (ESAR) prosthetic feet effective?

The magnitude and the distribution of the energy stored and a series of stress and strain parameters were analysed for the test device using the proposed approach. The novel methodology proposed may act as an effective tool for the design, analysis and prescription of energy storage and return (ESAR) prosthetic feet.

Does a Proflex foot store more energy during stance or push-off?

The Pro-Flex foot stored more energy during stance than the Vari-Flex foot ( $p = 0.022$ ), returned more energy ( $p = 0.045$ ), more of that energy was delivered during push-off ( $p = 0.023$ ), and these results occurred with large effect sizes and observed power (Table 1).

What are ESAR feet?

In a healthy human limb during walking by generating the highest joint power at the ankle in a gait cycle. human gait, the energy storage and return (ESAR) feet have been developed for walking with a prosthesis. unloading periods of the stance phase of gait. Users of lower limb prostheses have shown a preference for ESAR feet as

Does a pro-Flex provide the same energy as a sound ankle-foot?

The ability of the Pro-Flex to deliver the same amount of energy for propulsion as the sound ankle-foot was because the sound ankle-foot reduced its output during the downhill condition. The amount of energy absorbed by the either prosthetic foot was significantly less than the sound ankle-foot ( $p < 0.001$ ) (Fig. 3).

What causes low energy storage?

The low energy storage of the pad may be due to the insignificant strain and stress it underwent (Figures 8 and 9), and its low elastic modulus (Table 1). Although the polyurethane foam released a degree of energy return. Also, Table 2 shows the maximum energy stored by the SACH foot at HL. As a test scenario, it may still be a minuscule 3.2 W.
