## What is a battery energy storage system?

A battery energy storage system (BESS) is an electrochemical device that charges (or collects energy) from the grid or a power plant and then discharges that energy at a later time to provide electricity or other grid services when needed.

What happens during the charging period of a battery?

During the charging period, the system prioritizes charging the battery first from PV, then from the power grid until the cut-off SOC is reached. After reaching the cut-off SOC, the battery will not discharge, and the photovoltaic output will also be normal. During the discharge period, the battery is used for self-consumption.

How long does a battery storage system last?

For example, a battery with 1 MW of power capacity and 4 MWh of usable energy capacity will have a storage duration of four hours. Cycle life/lifetime is the amount of time or cycles a battery storage system can provide regular charging and discharging before failure or significant degradation.

Why should a battery energy storage system be co-located?

In doing so, BESS co-location can maximise land use and improve efficiency, share infrastructure expenditure, balance generation intermittency, lower costs, and maximise the national grid and capacity. The battery energy storage system can regulate the frequency in the network by ensuring it is within an appropriate range.

How does the state of charge affect a battery?

The state of charge influences a battery's ability to provide energy or ancillary services to the grid at any given time. Round-trip eficiency, measured as a percentage, is a ratio of the energy charged to the battery to the energy discharged from the battery.

How often do EV batteries need to be charged?

For example, if the DDD of mid-size BEV (with a 312 km EV range) increases from 75 km to 625 km, and the battery needs to be charged more frequently from 1 time per four days to 2 times per day. We calculate battery SoC under three EV states: driving, charging, and parked.
