Comsol energy storage density

How do I choose the right COMSOL product?

To determine the right combination of products for your modeling needs,review the Specification Chart and make use of a free evaluation license. The COMSOL Sales and Support teams are available for answering any questions you may have regarding this. Try modeling a packed bed thermal energy storage system in COMSOL Multiphysics®.

What are thermal energy storage units?

Thermal energy storage (TES) units are used to accumulate thermal energy from solar,geothermal,or waste heat sources. The simplest TES units are built from water tanks,where the solar energy is stored as sensible heat. These systems are called sensible heat storage (SHS) units.

What is a 1D model of a thermal energy storage system?

1D model of a thermal energy storage (TES) system consisting of a packed bed of pellets. Three approaches for heat transfer in porous media are compared: This model example illustrates applications of this type that would nominally be built using the following products: however,additional products may be required to completely define and model it.

Which energy density is the most expensive?

The highest energy density from the mentioned has the storage by Zauner et al. 17. It is mostly because over 80% of the storage is occupied by PCM. Furthermore, a higher temperature difference plays some role. From the presented storages, it is the most complicated one from the manufacturing point of view and thus probably the most expensive.

Why is energy density not a priority?

The design by Zauner et al. 18 has even lower energy density, but it is fair to say that it is a hybrid latent-sensible storage and so energy density was not a priority. The highest energy density from the mentioned has the storage by Zauner et al. 17. It is mostly because over 80% of the storage is occupied by PCM.

Is heat energy density a good measure of Design Effectiveness?

Therefore,the overall heat energy density might be a good measure of the design effectiveness. The presented design has about 9% higher heat energy density then the design by Xu et al. 8 despite they used PCM with higher latent heat per unit volume (298 MJ m -3 vs 211 MJ m -3).
