Can air be used as a storage medium for thermal energy systems?

The use of air as heat transfer fluid and a packed bed of rocks as storage medium for a thermal energy system (TES) can be a cost-effective alternative for thermal applications. Here, a porous media turbulent flow (standard) and heat transfer (local thermal non-equilibrium) model is used to simulate the discharge cycle of such system.

How to optimize the use of thermal energy storage technologies?

To optimize the use of thermal energy storage technologies, like sensible heat storage water tanks, and to adequately design suitable control strategies, namely when to charge and discharge the tanks, state estimation, in case of inexistence of enough temperature sensors or in case of failure of any of them, is crucial.

Are fast buoyancy effects associated with charging and discharging?

Fast buoyancy effects are associated with charging and discharging. According to, to include fast buoyancy effects in the heat storage tank model, we first need to consider whether the heat storage tank is based on direct or indirect operation.

How does discharge flow velocity affect charge efficiency?

Specifically for the discharge, the results indicated that increasing discharge flow velocity made the discharge efficiency get closer to the charge efficiency for all cases. Increasing the porosity of the system was also beneficial for the effectiveness of the discharge even with an equal amount of solid in the system ( ).

How does a storage tank work?

In early examples, practiced by BAC, Evapco, and others for modules of roughly 500 to 1,500 ton-hrs (1.8 to 5.3 MWh), a rectangular storage tank flooded with water contains a serpentine coil of metal pipe through which refrigerant is circulated and vaporized, forming ice on the pipe exterior.

Which tank employs a direct charging and discharging topology?

1. The 50 m<sup>3</sup> tank from the first case study. This tank, referred henceforth as Tank A, employs a direct charging and discharging topology. The tank is depicted in Fig. 1. 2. One of the two 12 m<sup>3</sup> tanks from the second case study. This tank, referred henceforth as Tank B, also employs a direct charging and discharging topology.

The facility operates the hydraulic system of the buffer storage tank only during the transitional period. The main goal is to reduce energy consumption by changing the operating strategy of the

A crucial component in this process is the buffer tank which is a giant thermal battery. These well-insulated tanks, filled with water or a material with high thermal capacity, store the captured energy with minimal heat

The three operating scenarios examined show that the annual energy consumption and the number of operating hours of the chiller can be reduced by using the buffer tank with the right strategy.
