

Is morphology a factor determining the CE and cycle life of lithium batteries?

It is widely accepted that the morphology is one of the determinantal factors for the CE and cycle life of Li metal batteries 4,5.

Can electron microscopy imaging be used in characterization of battery materials?

This review aims to cover both advanced electron microscopy imaging techniques and their applications in the characterization of battery materials involving cathode, anode, and separator and solid electrolyte interphase (SEI).

How do interfaces affect morphological changes in a battery system?

The dynamic evolution of interfaces induces significant morphological changes which may be observed by in situ SEM and TEM on battery systems with low vapor pressure-based electrolytes--for instance, ionic liquid, polymer, and ceramic-based electrolytes.

Why is data analysis important for characterization of battery interfaces?

In addition to HTS that allows for the fast screening of multiple chemistries and/or cell components, the correct analysis of data generated from battery testing is evidently an integral part of characterizing battery interfaces.

How has battery technology changed our understanding of battery materials?

The use of these techniques has led to significant advances in our understanding of battery materials, including the identification of new phases and structures, the study of interface properties, and the characterization of defects and degradation mechanisms.

Which spectroscopy techniques are used in battery characterization?

In this second category, conventional transient or stationary techniques like voltammetry, galvanostatic, or impedance spectroscopy, which are routinely used for the characterization of electrode materials, have been specifically developed for battery applications.
