

How to increase energy storage density of inorganic materials?

Element doping is the simplest way to increase the energy storage density of inorganic materials. It is greatly effective to increase the relaxation and reduce the remanent polarization by doping (La, Sm, Zr, etc.), which is beneficial for the energy storage density and efficiency [83,84,85].

Why are inorganic layers important?

The deposition and insertion of inorganic layers improves the dielectric constant, energy storage properties, and high temperature stability of the composites [,,]. This is in line with the market demand for excellent thermal ability and high energy storage performance dielectric materials.

What are the different types of energy storage materials?

According to the types of dielectrics, dielectric energy storage materials include ceramics, thin films, organic polymers, and filler-polymer composites. The research status overviews of different kinds of energy storage materials are summarized here. Energy storage ceramics are the most studied materials.

Are inorganic PCMs a good choice for thermal energy storage?

Although inorganic PCMs have relatively higher thermal conductivity (up to about 1 W/m-K) than pure organic PCMs, the thermal conductivity is still unacceptably low in many thermal energy storage systems, making it a challenge for their applications.

Are organic-inorganic layered composites suitable for electrostatic energy storage applications?

The novel compositions and architectures of organic-inorganic layered composites with ultrahigh energy storage density and excellent thermal stability were summarized. A new and constructive strategy for the development of high-end layered dielectric materials for electrostatic energy storage applications was provided. 1. Introduction
