

Storage systems with higher energy density are often used for long-duration applications such as renewable energy load shifting [10]. Table 3. Technical characteristics of energy storage technologies. Double-layer capacitor. Vented versus sealed is not specified in the reference. Energy density evaluated at 60 bars.

Thermochemical energy storage systems utilize chemical reactions that require or release thermal energy. They have three operating stages: endothermic dissociation, storage of reaction products, and exothermic reaction of the dissociated products (Fig. 7). The final step recreates the initial materials, allowing the process to be repeated.

Thermochemical energy storage systems exhibit higher storage densities than sensible and latent TES systems, making them more compact. This is a beneficial characteristic in applications where storage space is limited or expensive.

Since one type of energy storage systems cannot meet all electric vehicle requirements, a hybrid energy storage system composed of batteries, electrochemical capacitors, and/or fuel cells could be more advantageous for advanced vehicular energy storage systems.

Short-term energy storage systems often have smaller capacities and retain heat for a period of a few hours to a few days. Such systems can also be used to store solar thermal energy during the day for use during cooler hours when heating is needed.

Since energy losses during storage are smaller for thermochemical energy storage than for sensible or latent TES, thermochemical energy storage has good potential for long-term storage applications. Thermochemical energy storage systems nonetheless face various challenges before they can achieve efficient operation.
