

Can programmable electrochemical energy storage devices power future wearable and biointegrated electronics?

Leveraging these customizable electrochemical energy storage devices will shed light on smarter programmable electrochemical energy storage devices to power future wearable and biointegrated electronics. What is a customizable electrochemical energy storage device?

A customizable electrochemical energy storage device is a key component for the realization of next-generation wearable and biointegrated electronics. This Perspective begins with a brief introduction of the drive for customizable electrochemical energy storage devices.

What is energy storage materials?

Energy Storage Materials is an international multidisciplinary journal for communicating scientific and technological advances in the field of (such as in metal-O₂ battery). It publishes comprehensive research articles including full papers and short communications, as well as topical feature articles/reviews by leading experts in the field.

What is a programmable material?

Henceforth, the term "programmable" will denote materials engineered to be highly dynamic, either in shape and/or in physical/functional properties such as color, stiffness, density, and damping capacity, which can be altered on-demand -either autonomously or through user inputs- and in a precise, pre-established sequence post-fabrication.

Which materials can be used for energy storage?

Materials possessing these features offer considerable promise for energy storage applications: (i) 2D materials that contain transition metals (such as layered transition metal oxides 12, carbides 15 and dichalcogenides 16) and (ii) materials with 3D interconnected channels (such as T-Nb₂O₅ (ref. 17) or MnO₂ spinel 12).

What materials have programmable electrical properties?

Fig. 13. Examples of materials with programmable electrical properties. (A) Sensor for monitoring body signals, based on a silk fibroin-based hydrogel that detect a wide range of strains and respond by changing their electrical resistance as well as output voltage signal. The sensor was attached to the skin for 24 h to test its biocompatibility.
