

How to design a pumping station?

Apart from other aspects, the first step consists of determining the design point. The pumping station must provide the maximum required flow ( $Q_{max}$ ) and the corresponding maximum head ( $H_{max}$ ). At this point, two different variables must be considered: model of the pump and number of them.

Can drinking water pump station design and operation reduce energy consumption?

This research developed a guidance manual focused on drinking water pump station design and operation to minimize energy consumption.

Why do we need a new pumping station design?

Abstract Uncertain climate change and increasing energy cost become the pressing challenges for either new design or refurbishment of pumping stations in water and wastewater industries. These challenges make more complex to the design work for optimal solutions in meeting current scenarios, unplanned operational behaviors and unpredicted failure.

How should a new pumping station be planned?

Avoid location of new pumping station close to sea or river and any locations with potential risk of flooding at a frequency of more than 1-in-30 years (Water UK, 2019). Ensure layout of new pumping station to work with the contours of the land to manage exceedance flow safety and any uncontrolled overload flow from adjacent sites (Water UK, 2019).

How to transport pumping station discharge?

The method and structures required to transport pumping station discharge are determined largely by the type of protection works adjacent to the pumping station, the location of the station with relation to existing sewers, and the desirability of avoiding layouts involving pressure conduits, especially under levees on yielding foundations.

How a water treatment plant pumping station works?

Draw water from a natural source like a river, lake or reservoir and pumping into the water treatment plants or directly into distribution network for supply to end users Type 2 Water treatment plant pumping station Draw water within water treatment plant to move water through the treatment process before sending it to the distribution network.
