

Why is strontium titanate a requirement for galvanic cells?

This is a requirement for galvanic cells and determines the characteristic cell voltage. Strontium titanate is a model material, crystallizing in cubic structure with space group  $P\ m\ 3\ \bar{m}$ , which hosts a manifold of excellent physical properties based on its crystallographic and electronic structure.

Is a rechargeable  $\text{SrTiO}_3$  energy storage possible?

A comprehensive thermodynamic deduction in terms of theoretical energy and entropy calculations indicate an exergonic electrochemical reaction after the electric field is switched off. Based on that driving force the experimental and theoretical proof of concept of an all-in-one rechargeable  $\text{SrTiO}_3$  single crystal energy storage is reported here.

Is  $\text{SrTiO}_3$  a lead-free material for high density energy storage?

In recent years, the  $\text{SrTiO}_3$  system has been considered to be one of the promising lead-free materials for high density energy storage applications due to its relatively high  $E_b$  ( $> 0.2 \text{ MV/cm}$ ), low dielectric loss tangent ( $< 1\%$  at 1 kHz) and stable temperature capacitance [51,52].

Can strontium bromide be encapsulated in a mesoporous MOF?

For the first time, strontium bromide has been successfully encapsulated in a mesoporous MOF (i.e., MIL-101 (Cr)) with a high salt content of 63 wt. %. This salt is promising for residential heat storage applications and had never been encapsulated with such a high rate in a composite material.

What causes redistribution of oxygen vacancies in a strontium titanate single crystal?

Redistribution of oxygen vacancies in a strontium titanate single crystal is caused by an external electric field. We present electrical measurements during and directly after electroformation, showing that intrinsic defect separation establishes a non-equilibrium state in the transition metal oxide accompanied by an electromotive force.

How are strontium titanate single crystals electroformed?

Electroformation of the strontium titanate single crystals was performed using electric fields in the order of  $10^6 \text{ V m}^{-1}$  where the electric current flow through the crystal was recorded. Electrical measurements were performed in complete absence of light. Time-dependent current measurements have been conducted with a Keithley 4200 SCS. 3. Results
