How does a grounding switch work?

The grounding switch operates to provide a deliberate ground fault on one phase of the high-voltage bus supplying the power transformer, disrupting the normally balanced 120° phase shifted three-phase system by effectively removing one phase and causing the other two phases to become 180° phase shifted relative to each other.

Why is grounding important in electrical systems?

However, there is another crucial element in electrical systems that is often overlooked: the connection to the earth. The electrical connection to the earth, commonly referred to as "grounding" or "earthing," plays a vital role in ensuring the safety and stability of electrical systems.

What happens if an electrical system is grounded?

This means that you will not receive an electrical shock as any excess electricity is discharged through the earth. Most electrical systems are grounded to protect users and systems in the event of an electrical fault, earth fault, or a build-up of the level of electricity.

Should switchgear panels be energized before grounding?

To decrease risk of personal injury, workers should stay away from open energized switchgear panels prior to proper equipment grounding. Any time panels are removed and energized components are exposed, the chance for arc flash or electrocution increases. An additional layer of safety: Integral grounding switches

Why do switchgear operators use grounding switches?

Personnel that operate switchgear with grounding switches have a higher degree of confidence in applying ground without having to open switchgear compartments first.

What is an internal grounding switch?

The purpose of an internal grounding switch is to provide a process to ground MV switchgear before removing panel covers and exposing personnel.
